About the Author

Timothy Boronczyk is a native of Syracuse, NY, where he works as a freelance developer, programmer and technical editor. He has been involved in web design since 1998 and over the years has written several articles and tutorials on PHP programming. Timothy holds a degree in software application programming and recently started his first business venture, Salt City Tech (www.saltcitytech.com). In his spare time, he enjoys photography, hanging out with friends, and sleeping with his feet hanging off the end of his bed. He's easily distracted by shiny objects.

About the Contributor

Martin E. Psinas is a recognized security expert and valued member of the open-source community. He has been contracted as a technical editor, code auditor, and is a published author with Pearson Education as well as the #1 PHP magazine, *PHP | Architect*. In his free time, he maintains his personal web site and is a volunteer administrator/contributor at codewalkers.com — a resource for PHP & MySQL developers. Martin interacts frequently with the leaders of the PHP project as well as PHP User's Groups.

Introduction

I'm especially amazed at how the Internet has grown and evolved over the past decade or so. It has grown from a collection of static text documents connected by a few hyperlinks to a platform for delivering rich, distributed applications. And when it comes time to develop these web-based applications, many programmers are choosing PHP and MySQL.

In this book, I present basic code for 12 PHP-powered projects that you can use and extend however you wish. I have tried to write them so the code can be easily reused in future applications, but in some instances the entire application can be reused as well!

I've enjoyed the opportunity to write and share with you this information and I hope you have just as much fun reading it and learning from it. More importantly, I hope you find good, practical uses for the projects found within this book.

Who This Book Is For

I present basic yet functional projects for you to implement and extend in any way you see fit. That very fact assumes you know the fundamentals of programming in PHP and general web development. This book is not a textbook. Still, you do not need to be an advanced PHP programmer to gain much by reading it. New programmers should find this book helpful as it will give them guidance in how to program different applications. The 12 projects may even serve to ignite their curiosity and spur them to write 12 more projects of their own. Intermediate and more experienced programmers will find this book helpful because they are able to take the projects I present, modify them and apply them to their real-world needs.

Some projects build upon previous projects, so while you don't have to read the book from cover to cover, I do suggest reading all relevant chapters (or at least the pertinent sections) regardless of your skill level. For example, in Chapter 7, I present an online photo album, but pictures are uploaded using the AJAX file manager presented in Chapter 6. Both projects are laid out in the manner presented in Chapter 1.

What This Book Covers

The code in this book was written for MySQL 5.0 Community Server and PHP version 5.2.5, so essentially I am covering those releases or greater. Additional modification may be necessary if you plan on using earlier releases.

How This Book Is Structured

Each chapter is organized so following projects can build upon earlier projects. Here's a brief rundown of what you can look forward to in the following chapters:

Chapter 1: User Registration

Create a basic user registration system

Reusable components: configuration/include files, 401.php, User class

Chapter 2: Community Forum

Expand on user registration system to create a community forum with user privileges and threaded posts

Reusable components: JpegThumbnail class, BBCode class

Chapter 3: Mailing List

Create a mailing list with control address and digest mailings

Reusable components: POP3Client class

Chapter 4: Search Engine

Build a custom search engine for your own site

Reusable components: entire application

Chapter 5: Personal Calendar

Write a personal calendar utility to keep yourself organized

Reusable components: entire application

Chapter 6: AJAX File Manager

Create an AJAX-ified file upload and directory viewer

Reusable components: entire application (this project introduces AJAX which will be used in subsequent projects)

Chapter 7: Online Photo Album

Create a file-based image gallery with automatically generated thumbnails that supports JPEG and QuickTime formats.

Reusable components: MovThumbnail class

Chapter 8: Shopping Cart

Write a categorized shopping cart

Reusable components: ShoppingCart class

Chapter 9: Web Site Statistics

Log site traffic and collect information about site visitors to make better business decisions

Reusable components: PieChart class, BarChart class

Chapter 10: News/Blog system

Build a news or blog system with comments and RSS feed

Reusable components: entire application (project also introduces reusable components such as YUI calendar and TinyMCE rich text control)

Chapter 11: Shell Scripts

Write and run management scripts

Reusable components: `CommandLine` class, `recurs_copy()` function

Chapter 12: Security and Logging

Learn about SQL injection, path traversal, weak authentication, and XSS and how to avoid them

Reusable components: `write_log()` function, `view_log.php`, record delete script

What You Need to Use This Book

Since you'll be writing PHP code, you'll need an editor to do so. Whichever you choose to use is a matter of preference. Additionally, you will also need a server running PHP and MySQL to host your applications and a web browser to access them. What you use is a matter of choice. I've provided instructions for setting up applications on both Unix and Windows platforms when necessary, for example the Mailing List application in Chapter 3, which runs as a scheduled job.

Personally, I used `vi` to write code, hosted the projects on a server running Slackware Linux and accessed them from a Windows XP computer using Firefox.

Some of the projects make use of special extensions to PHP, although I have tried to keep this to a minimum. For example, the Search Engine application presented in Chapter 4 uses the `pspell` extension. If additional functionality was needed which could only be provided by an extension, I avoided third-party extensions so that if you want to install a particular extension you only need to look as far as the official documentation at `www.php.net`. The relevant extensions are mentioned in the appropriate chapters.

Conventions

To help you get the most from the text and keep track of what's happening, I've used a number of conventions throughout the book.

As for styles in the text:

- ❑ We *highlight* new terms and important words when we introduce them.
- ❑ We show keyboard strokes like this: `Ctrl+A`.
- ❑ We show file names, URLs, and code within the text like so: `persistence.properties`.
- ❑ We present code in two different ways:

We use a monofont type with no highlighting for most code examples.

We use gray highlighting to emphasize code that's particularly important in the present context.

Source Code

As you work through the examples in this book, you may choose either to type in all the code manually or to use the source code files that accompany the book. All of the source code used in this book is available for download at www.wrox.com. When at the site, simply locate the book's title (either by using the Search box or by using one of the title lists) and click the Download Code link on the book's detail page to obtain all the source code for the book.

Because many books have similar titles, you may find it easiest to search by ISBN; this book's ISBN is 978-0-470-19242-9.

Once you download the code, just decompress it with your favorite compression tool. Alternately, you can go to the main Wrox code download page at www.wrox.com/dynamic/books/download.aspx to see the code available for this book and all other Wrox books.

Errata

We make every effort to ensure that there are no errors in the text or in the code. However, no one is perfect, and mistakes do occur. If you find an error in one of our books, like a spelling mistake or faulty piece of code, we would be very grateful for your feedback. By sending in errata you may save another reader hours of frustration and at the same time you will be helping us provide even higher quality information.

To find the errata page for this book, go to www.wrox.com and locate the title using the Search box or one of the title lists. Then, on the book details page, click the Book Errata link. On this page you can view all errata that has been submitted for this book and posted by Wrox editors. A complete book list including links to each book's errata is also available at www.wrox.com/misc-pages/booklist.shtml.

If you don't spot "your" error on the Book Errata page, go to www.wrox.com/contact/techsupport.shtml and complete the form there to send us the error you have found. We'll check the information and, if appropriate, post a message to the book's errata page and fix the problem in subsequent editions of the book.

User Registration

Offering account registration and user logins is a great way of giving users a sense of individuality and serving tailored content. Such authentication is often at the very heart of many community-oriented and e-commerce web sites. Because this functionality is so useful, the first application I present is a user registration system.

From a functional perspective, the system will allow users to create accounts. Members must provide an e-mail address that they can use to validate their registration. Users should also be able to update their passwords and e-mail addresses and reset forgotten passwords. This is pretty standard functionality and what the web users of today have come to expect.

From an architectural standpoint, the directory holding your code should be logically organized. For example, support and include files should be kept outside of a publically accessible directory. Also, user records should be stored in a database. Since there are a large number of tools designed to view and work with data stored in relational databases such as MySQL, this affords transparency and flexibility.

Plan the Directory Layout

The first step is to plan the directory structure for the application. I'm going to recommend you create three main folders: One named `public_files` from which all publicly accessible files will be served, another named `lib` to store include files to be shared by any number of other files, and finally a `templates` folder to store presentation files. Although PHP will be able to reference files from anywhere in your setup, the web server should only serve files from the `public_files` folder. Keeping support files outside of the publicly accessible directory increases security.

Inside the `public_files` I also create `css` to store any style sheets, `js` for JavaScript source files and `img` for graphic files. You may want to create other folders to keep yourself organized. One named `sql` to store MySQL files would be a good idea, `doc` for documentation and development notes and `tests` to store smoke test or unit testing files.

Planning the Database

In addition to planning the directory layout, thought needs to be given to the database layout as well. The information you choose to collect from your users will depend on what type of service your site offers. In turn, this affects how your database tables will look. At the very least a unique user ID, username, password hash, and e-mail address should be stored. You will also need a mechanism to track which accounts have been verified or are pending verification.

```
CREATE TABLE WROX_USER (
  USER_ID      INTEGER UNSIGNED NOT NULL AUTO_INCREMENT,
  USERNAME     VARCHAR(20)       NOT NULL,
  PASSWORD     CHAR(40)         NOT NULL,
  EMAIL_ADDR   VARCHAR(100)     NOT NULL,
  IS_ACTIVE    TINYINT(1)       DEFAULT 0,

  PRIMARY KEY (USER_ID)
)
ENGINE=MyISAM DEFAULT CHARACTER SET latin1
COLLATE latin1_general_cs AUTO_INCREMENT=0;

CREATE TABLE WROX_PENDING (
  USER_ID      INTEGER UNSIGNED NOT NULL,
  TOKEN        CHAR(10)         NOT NULL,
  CREATED_DATE  TIMESTAMP       DEFAULT CURRENT_TIMESTAMP,

  FOREIGN KEY (USER_ID)
    REFERENCES WROX_USER(USER_ID)
)
ENGINE=MyISAM DEFAULT CHARACTER SET latin1
COLLATE latin1_general_cs;
```

I have allocated 40 characters of storage for the password hash in `WROX_USER` as I will use the `sha1()` function which returns a 40-character hexadecimal string. You should never store the original password in the database — a good security precaution. The idea here is that a hash is generated when the user provides his or her password for the first time. The password given subsequently is hashed using the same function and the result is compared with what's stored to see if they match.

I set the maximum storage length for an e-mail address at 100 characters. Technically the standards set the maximum length for an e-mail address at 320 (64 characters are allowed for the username, one for the @ symbol and then 255 for the hostname). I don't know anyone that has such a long e-mail address though and I have seen plenty of database schemas that use 100 and work fine.

Some other information you may want to store are first and last name, address, city, state/province, postal code, phone numbers, and the list goes on.

The `WROX_PENDING` table has an automatically initializing timestamp column, which lets you go back to the database and delete pending accounts that haven't been activated after a certain amount of time. The table's columns could be merged with `WROX_USER`, but I chose to separate them since the pending token is only used once. User data is considered more permanent and the `WROX_USER` table isn't cluttered with temporary data.

Writing Shared Code

Code that is shared by multiple files should be set aside in its own file and included using `include` or `require` so it's not duplicated, which makes maintaining the application easier. Where possible, code that might be useful in future applications should be collected separately as functions or classes to be reused. It's a good idea to write code with reusability in mind. `common.php` contains shared code to be included in other scripts in the application to establish a sane baseline environment at runtime. Since it should never be called directly by a user, it should be saved in the `lib` directory.

```
<?php
// set true if production environment else false for development
define ('IS_ENV_PRODUCTION', true);

// configure error reporting options
error_reporting(E_ALL | E_STRICT);
ini_set('display_errors', !IS_ENV_PRODUCTION);
ini_set('error_log', 'log/phperror.txt');

// set time zone to use date/time functions without warnings
date_default_timezone_set('America/New_York');

// compensate for magic quotes if necessary
if (get_magic_quotes_gpc())
{
    function _stripslashes_rcurs($variable, $stop = true)
    {
        $clean_data = array();
        foreach ($variable as $key => $value)
        {
            $key = ($stop) ? $key : stripslashes($key);
            $clean_data[$key] = (is_array($value)) ?
                stripslashes_rcurs($value, false) : stripslashes($value);
        }
        return $clean_data;
    }
    $_GET = _stripslashes_rcurs($_GET);
    $_POST = _stripslashes_rcurs($_POST);
    // $_REQUEST = _stripslashes_rcurs($_REQUEST);
    // $_COOKIE = _stripslashes_rcurs($_COOKIE);
}
?>
```

You may not always have control over the configuration of your server so it is wise to specify some common directives to make your applications more portable. Setting error reporting options, for example, lets you display errors while in development or redirect them in a production environment so they don't show to the user.

Magic quotes is a configuration option where PHP can automatically escape single quotes, double quotes, and backslashes in incoming data. Although this might seem useful, assuming whether this directive is on or not can lead to problems. It's better to normalize the data first and then escape it with `addslashes()` or `mysql_real_escape_string()` (preferably the latter if it's going to be stored in the

Chapter 1: User Registration

database) when necessary. Compensating for magic quotes ensures data is properly escaped *how* you want and *when* you want despite how PHP is configured, making development easier and less error-prone.

Establishing a connection to a MySQL database is a common activity which makes sense to move out to its own file. `db.php` holds configuration constants and code to establish the connection. Again, as it is meant to be included in other files and not called directly, it should be saved in `lib`.

```
<?php
// database connection and schema constants
define('DB_HOST', 'localhost');
define('DB_USER', 'username');
define('DB_PASSWORD', 'password');
define('DB_SCHEMA', 'WROX_DATABASE');
define('DB_TBL_PREFIX', 'WROX_');

// establish a connection to the database server
if (!$GLOBALS['DB'] = mysql_connect(DB_HOST, DB_USER, DB_PASSWORD))
{
    die('Error: Unable to connect to database server.');
```

The `DB_HOST`, `DB_USER`, `DB_PASSWORD` and `DB_SCHEMA` constants represent the values needed to establish a successful connection to the database. If the code is put into production in an environment where the database server is not running on the same host as PHP and the web server, you might also want to provide a `DB_PORT` value and adjust the call to `mysql_connect()` appropriately.

The connection handle for the database is then stored in the `$GLOBALS` super global array so it is available in any scope of any file that includes `db.php` (or that is included in the file that has referenced `db.php`).

Prefixing table names helps prevent clashes with other programs' tables that might be stored in the same schema and providing the prefix as a constant makes the code easier to update later if it should change, since the value appears just in one place.

Common functions can also be placed in their own files. I plan to use this `random_text()` function, for example, to generate a CAPTCHA string and validation token so it can be saved in a file named `functions.php`.

```
<?php
// return a string of random text of a desired length
function random_text($count, $rm_similar = false)
{
    // create list of characters
    $chars = array_flip(array_merge(range(0, 9), range('A', 'Z')));
```

```

// remove similar looking characters that might cause confusion
if ($rm_similar)
{
    unset($chars[0], $chars[1], $chars[2], $chars[5], $chars[8],
        $chars['B'], $chars['I'], $chars['O'], $chars['Q'],
        $chars['S'], $chars['U'], $chars['V'], $chars['Z']);
}

// generate the string of random text
for ($i = 0, $text = ''; $i < $count; $i++)
{
    $text .= array_rand($chars);
}

return $text;
}
?>

```

An important rule when programming no matter what language you're using is to never trust user input. People can (and will) provide all sorts of crazy and unexpected input. Sometimes this is accidental, at other times it's malicious. PHP's `filter_input()` and `filter_var()` functions can be used to scrub incoming data, though some people still prefer to write their own routines, as the filter extension may not be available in versions prior to 5.2.0. If you're one of those people, then they can be placed in functions.php as well.

User Class

The majority of the code written maintaining a user's account can be encapsulated into one data structure, making it easy to extend or reuse in future applications. This includes the database interaction logic, which will make storing and retrieving information easier. Here's `User.php`:

```

<?php
class User
{
    private $uid;    // user id
    private $fields; // other record fields

    // initialize a User object
    public function __construct()
    {
        $this->uid = null;
        $this->fields = array('username' => '',
                              'password' => '',
                              'emailAddr' => '',
                              'isActive' => false);
    }

    // override magic method to retrieve properties
    public function __get($field)

```
