Preface

The theory of plate tectonics was introduced to China in the early 1970s. Over the last thirty years, both Chinese and foreign geoscientists have undertaken many studies which contributed to our understanding of the tectonics of the Chinese continent, by systematically analysing and summarising considerable amount of data accumulated for regional geodetic surveys, and by improving the methods of research. These studies concerned not only the distribution and geometry of tectonic structural units and their deformation, but also the lineaments, evolution and causes of rock deformation and movement of the lithospheric plates. As a result of these studies, many new and surprising phenomena have been discovered, and many new concepts have also been developed. Research has progressed from purely qualitative assessments of behaviour of deformation with the focus on initiation or movement associated to numerical calculations providing more quantitative estimates. Concepts have also evolved from the presumption that the Earth's crust is essentially stable to an appreciation of it as in constant movement. These aspects will be discussed in this book.

Tectonics is now an essential component of studies in earth sciences, providing the scientific basis for the discernment and exploitation of new mineral deposits and energy resources, the prediction of the environment and the prediction and reduction of the effects of natural hazards. There is an urgent need to summarise systematically the advances in recently acquired tectonic data for scientific research, explanation of mineral deposits and energy resources and the protection of the environment.

The practical and theoretical basis for studies in tectonics is provided by developments in: (1) Regional geodetic studies; (2) Tectonic models; (3) Methods of tectonic analysis; (4) Concepts of tectonic evolution.

Regional geodetic studies provide the foundation for the study of tectonics and have been conducted in China since 1946. Regional neotectonic maps at 1:1,000,000 scale were compiled for the main part of Chinese continental territory in 1948, 1949 and at 1:200,000 scale from 1950s to 1980s (national and provincial neotectonic maps of China, 1984–1995). Based on these data, tectonic units have been defined, discussed and analysed carefully in each region (Guangdong (1934–1937), also known as Hunan (1948, 1950, 1964, 1980, 1979, 1984, 1985); Gansu and Kweichow (1934–1937); Inner Mongolia (1950); Shaanxi et al., 1980, 1990, 1995, 2000; Yunnan and Tibet, 1980; Chongqing (1994); Chongqing et al., 2002). Local and regional tectonic characteristics are now well understood. In Chinese geoscientists recognised larger scale tectonic regions and integrated the regional features into the tectonic development of the Chinese continent can survive better than the geoscientists thought as a whole. However, the use of fixed tectonic units does not provide an appropriate basis for the description of the tectonics of China, as a result of the course of tectonic evolution the effective tectonic units have changed through time.

Tectonic models have provided important concepts for understanding tectonics. Le Goff (1889–1977) also known as Le Goff, 1926, 1947, 1960 proposed a structural system based on a combination of the features of rock deformation and the different types of stress (‘epissial’ type 1 (for ‘schalen’) type

linear structural system; parallel structural system; longitudinal structural system; frame structure system, etc. However, this classification will not be used in the following chapters.

Most recent monographs and textbooks on tectonics (e.g. Currier, 1992, 1993; Kearney and Yin, 1994; Van der Pluijm and Marsh, 1994; Doreks, 2001; Brackley, 2011) used the same tectonic models: convergent tectonics (subduction, collision, indentation) and mass belts; Divergent tectonics (oceanic ridges, rifts, extension, basins, detachment) and metamorphic zone complexes; transform tectonics (transform and strike-slip faults); Inversion tectonics, unlike the earlier tectonic systems. The theoretical system emphasizes the mechanism and the components of each tectonic model, and is easy to be understood. However, this system does not place much emphasis on tectonic history. The system emphasizes the tectonic analysis of specific geological situations, but it is important to realize that geological sciences is essentially a historical science, and that many changes and many different tectonic events have affected the lithosphere from more than four billion years of Earth history.

It is not the intention for us to repeat the methods of tectonic analysis. However, only emphasizing the methods but never discussing the tectonic evolution in detail, as McW.P. (1992) did, has been proved ineffective.

Many monographs and papers emphasize the historical aspects of the tectonics of China have been published by Lin (1971, 1981, 1984, 1986, 1987, 1988, 1989), Liu (1971, 1981, 1989), Li (1982, 1984), Wang (1979, 1981, 1991, 1994), Ren (1978, 1981, 2003) and Kohn and Hodson (1993).

Here such as the concerned with "Historical Tectonics". On one hand, specialists engaged in historical tectonics pay more attention to structure type and the characteristics of geological formations and their origins, and analyze their lithological and paleontological characteristics, their geographic environments of formation and the origins of the sedimentary or igneous rocks, with emphasis on their historical evolution. On the other hand, tectonic modelers pay more attention to the transformation of rock bodies, the rock deformation, structural geometry, the stress and strain states, the habitats on the mechanism of deformation. Although most recent geoscientists engaged in tectonics agree that both geological formation and transformation should be studied, and that historical and mechanical analyses should be combined, due to the deficiencies of training, experience and the focus of their interests, these different approaches may have occurred naturally. Zhong WY (1979, 1984) and Li (1991, 1993) indicated that these approaches should be integrated in the study of the tectonics of China. The author considered that it is really important for geological science precedents in the present volume, though it is very difficult.

In this book, the author does his utmost to combine the studies of formation and transformation using the plate tectonic theory, together with historical and mechanical analyses. Abundant and recently reported geological, geochronological and geophysical research data are utilized to describe and discuss the sequence of tectonic events which have affected the Chinese continental lithosphere from the Archean to the Recent. Until the present time, it is difficult to achieve this aim because of the scarcity of data on the tectonic evolution.

In this volume, for understanding the tectonics of China, the author puts forward many new views: calculation of the thickness of the continental crust on the Sino-Korean plate and on the Arabian and Tibetan platelets to determine the velocities during motion; the Supercontinent of Gondwana once existed; the continental blocks were amalgamated to form the Chinese continent, establishing the plates during the Mesozoic; the 45°E-40°N lines were deformed on the Sino-Korean and Yanzagui plates respectively following the changes in the meridional and longitudinal distribution of the Chinese continental blocks during the Paleozoic; During the Late Paleozoic, most of the continental blocks were on the zangirte China collision and were connected with the Eurasian Plate; subsequently China continent was affected by intra plate deformation with three series of shortening in a north-Southward and East-West Period (260-230 Ma); Sichuan Plate Period (220-200 Ma); Tibetan Plate Period (14-20 Ma); two periods of shortening with a north-Southward Period (120-85 Ma); North-South Period (60-25 Ma); since 19.5 Ma (Quaternaries Period), the state of stress among the plates which constitute the Chinese continent has been nearly in equilibrium.

In this volume, the characteristics of many collision zones in the Chinese continent are analyzed in detail and discussed. The size of the thickness of the crust and the lithosphere beneath

is proposed for the "main body" of the *U-hat* sphere beyond the eastern Asia continent, which is possibly induced by the counterbalancing reaction of the continental East's extent to its respective oceanic world. The extent of the environment's reaction is recognized as the influence of a trap, an extent on duty of the Metaroad. Concrete on periods of time or realization in China is made understandable, which hypotheses about the dynamic mechanism that control global technological evolution.

This book was originally written by the author in Chinese and published by the Geostep-out Publishing House in Heilong in 2014. After incorporating many refinements, the book was translated into English, with a reduction of local terms and the removal of discussions which were not necessary to the foreign readers. Through translation, emphasis has been placed on areas such as terms and the major technical issues which have affected the Chinese continent. As references for the initial users, some well-known and following the suggestions of experts in specified fields. For the sake of the foreign readers, the articles and long titles of critical features have been reduced. Original data are recorded in Appendices, and a large number of references are cited, particularly from the Chinese literature, to facilitate further research in Chinese systems.

Acknowledgements

Academician Hongzhen Wang, an academic leader in the field of geosciences of China and Jilin University of Geosciences, has encouraged me to write this book, and his pioneering example influenced people's concern on the geotourism of geosciences of China.

The publication and success of many leading authors provided information for this book, including Academicians Chanwen Yu, Xuechun Xian, Tingdong Lu, Qiyang Gao, Qingsi Ding, Yaxhe Li, Zhai Hengxi, Zhong Zeng, in Ya, Dalai Zhenq, Lixian Ren, Liangwei Zhang, Guo Jidong, Liu, and Jiyu Li, etc. Professors Peiren Zhuang, Jin Bai, Xufu Qiao, Zhe Jiansi, Wei, Jingsi Liu, Linyong Lu, Changhe Zhao, Xianxi Qian, Guo He, Weiyun Ma, Xuehong Liu, Xianhua Meng, Ming Gu, Huihui Chen, Lei Zhao, Hongwei Ma, Hefa Liu, Wenqiang Wang, Dongyi Li, Huijin Zeng, Yachun Zhang, Shanchi Peng, Binyi Liang, Weiran Yang, Huijin Song, Jinyue Guo, Lufang Ma, Zhenyuan Wu, Hong Zhu, Zhibo Ren, Yingqun Zhang, Jinyu Li, Chongqi Wang, Yong Zhao, Yu Wang, Shaofeng Liu, Zhaohua Liu, and Dr. Yane Wang. I would like to thank Prof. Kent C. Cordia (University of New Mexico, USA), Liu Hai, Xuefu Qiao, Xianhua Meng, etc. for Jinhua Ye for providing figures and original data.

I am so grateful to the following people for the assistance in the parts of initial translation of this book: Dr. Zhang Xuesi for Chapters 2 and 3, Shoujun Zhang for Chapters 4 and 5, Mingming Wang for Chapters 8 and 9, Hanxian Wang for Chapters 10 and 11, Ruijun Li for Chapters 12 and 13, and Ulfarinn E. Weirald for Chapter 15.

I am especially grateful to Dr. A.J. Harvey (University of London, UK), who reviewed and polished the whole text. Without a kind help I could not have completed the manuscript in English.

Prof. M.H.P. Bui, Prof. Songqing Shi, Prof. H. Brindley, Dr. L.R.M. Coates, and Dr. J. K. Al. made many important comments and suggestions for this English edition. I would like to thank them all here.

Although the preparation of this book is the responsibility of the author, it clearly represents the collective literature and scientific creation of many researchers, colleagues and friends. I would like to express my heartfelt gratitude for their invaluable help and guidance.

Chapter 1 Introduction

Tectonics is a comprehensive subject area involved in Earth sciences concerning the historical development, evolution and origin of the earth. The aims of this subject are to determine the composition, the structure, the movements (tectonic deformation and displacement) and the evolution of the inner sphere of the solid earth, the lithosphere, and its relationship to activity in the interior, in the lower mantle and the core. This subject area is encompassed in the Theory of Plate Tectonics originating from the investigation of the ocean floor's structure, and combined with the theory of continental tectonics which until then had not universally accepted, evolved into a comprehensive theory of global tectonics (Kennedy

Fig. 1.1 Geological map of the People's Republic of China, with annotation of tectonic units (Springer, 2010, Beijing, China).

development of this subject area, encourage the cooperation of specialists involved in all the geoscience disciplines in the construction of a comprehensive Earth Sciences system.

In this book, the tectonics of China (Figs. 1.1 and 1.2) is dealt with as a sequence of tectonic events through geologic caltime. A comprehensive analysis of these events is based on the interpretation of records preserved in the rocks, which provides the evidence of the deformation produced by the movement of continental blocks during processes of the subduction, collision and finally convergence or the extension.

The tectonic systems developed out of these events are described in terms of rates of movement, orientation of tectonic stresses, major tectonic stress, and the nature and type of deformation. These tectonic and structural aspects are interpreted, together with the tectonic sedimentary, tectonic paleogeography and tectonic geomorphology, in the distribution of continental blocks and tectonic geological periods based on paleogeomorphology and deformation of paleogeographic units. As far as possible, these aspects are dealt with in a quantitative and a purely qualitative manner.

The Chinese continent is located in Eastern Asia (Fig. 1.1), composed of the Qinshui-Kangdian, Hetao Plateau, the Inner Mongolian, Ordos, Yunnan-Guizhou Plateau, the Dabai Mountains and Inner Mongolia and their surrounding mountains, and the eastern plains and hills. Generally, the Chinese continent consists of large continental craton and small blocks, which were gradually amalgamated to form the present Chinese continent. Unlike the Paleozoic, no tectonic blocks had been identified in the Chinese continent (Fig. 1.2) but it is divided into five tectonic domains, which will be discussed in detail in later chapters. The evolution of the Chinese continent was very different from the evolution of the North American, South American, Eurasian, African and Australian continental plates.

1.1. Tectonic Events

Concept: Before discussing tectonic events it is necessary to introduce the concept of the tectonic stratigraphic unit (or period), a term first proposed by geologists of the Soviet Union in the 1940s and introduced to the study of the tectonics of China by Zhang RY (1969). American geologists have also used a similar concept, the "tectonostratigraphic unit" more recently (Blümelberger and Carvers, 1996).

A tectonostratigraphic unit encompasses all the tectonostratigraphic features of a tectonic unit, distinctively by a particular type of deformation developed out of a particular tectonic series. In terms of time, a tectonostratigraphic unit represents a period in the tectonic evolution of the earth's surface in which it covers the area affected by a specific tectonic event (Fig. 1.2).

The boundary of a tectonostratigraphic unit is taken as a base of the sedimentation, marked by a regional angular unconformity which separates two tectonostratigraphic units (Fig. 1.2). The tectonostratigraphic unit lies between two angular regional unconformities. An angular regional unconformity is formed when an older rock unit deformed by either compressive or extensional is then uplifted, eroded and buried by younger rocks. The boundaries of tectonostratigraphic unit should not be taken as parallel unconformities or disconformities, as these do not represent significant tectonic events.

Different tectonostratigraphic units are characterized by different rates, styles and degrees of rock deformation, with different intensity, resulting from different stress orientations in different tectonic environments (Fig. 1.1). The geochronologic time occupied by a tectonostratigraphic unit is a "tectonic period". Each tectonic period can be divided into a stable (or "quiescent") period, which lasted for a relatively long series of time, and an active (or "catastrophic") period which occupied a much shorter period of time at the end of the tectonic series (Table 1.1). Each tectonic series commences with a long and stable period and ends with a short and active period. Movement of blocks, rock deformation and the related metamorphism and magmatism mainly constitute a tectonic event over the shorter and active tectonic period. By convention, these tectonic events are named after the area in which the tectonostratigraphic unit first occurs. However, for these events are named after their neotectonic or geomorphic evolution

Fig. 1.5. Three-stage tectonic evolution of a continental block (simplified by V. V. Kostin in his paper)

- I. Early orogenic folding and thrusting, development of a major tectonic zone with a well-stated tectonic polarity (marked by strike-slip faults) in the orogenic belt (Fig. 1.5, a);
- II. Transition to a zone of bidirectional tectonic development (Fig. 1.5, b);
- III. Stage of Cenozoic tectonic development in the course of tectonic shortening (Fig. 1.5, c).

intermittent comparison becomes easier. Conventional terms, derived from local tectonic periods or local events, are therefore used as far as possible in this book.

The degree and style of tectonism are different in the active and passive periods, but there is usually some connection and dependence, for example, the orientation of tectonic stresses and the direction of plate movement may be the same in both periods. However, the styles and rates of rock deformation are very different and the mineralogy of the masses are different and the types of magmatic activity and metamorphism are also different (Table 1.1).

1.7 Universal Tectonic Periods

Smith (1836–1846) proposed that there was a rhythm in the tectonic evolution of the Earth and that geological history was characterized by successive "series" (collectively "tectonic phases") which occurred at the same time in different parts of the world. In the 20th century this principle exerted a great influence on the development of tectonics. It has been used continually and reverse since it was first put forward. The German Soviet structural geologists (1940s) considered that rock deformation increased dramatically with changes in the tectonic regimes of geological time (see Vostokov et al. 1964), and some American geologists (e.g. Gilluly, 1949) were also disturbed with the concept of phases of universal orogeny, but

and their destruction of subduction zones along the margins of the oceans, it could easily be assumed that the processes of subduction and collision were also continuous processes. However, Linné (1989) and Bengtson (1992) hypotheses considered many disjunct tectonic roots before 1990's. When the much more detailed third edition of the tectonic-analytical map was published at the end of the 1990's (Cauze et al., 1999; Clarke and Kent, 1992; Vogt et al., 1993), analysis showed that since the White Cliffs event (500 Myr ago) tectonic plates and oceans had all expanded during the same six periods, with movements in different directions and at different velocities (Table 1.2) (Fig. 1.4). Sea floor spreading at velocities of several cm/y shows that the earth has the properties of a neo-plastic solid, while the processes during some periods of collision seem to fit with tectonics are in some extent connected with general contraction and contraction related elements of periodicity.

Evidence compiled in this volume shows that the tectonic evolution of the earth has not become linear with a uniform rate of change, but non-linear with periodic variations in the rate of change. The only present evidence it appears that the processes continue over a period of time at a more or less constant rate, but are then interrupted by sudden and catastrophic changes. Such qualitative and quantitative changes are characteristic of all evolutionary processes. As in Cuvier (1830) has explained tectonism, like all other geological processes, then it is considered in terms of non-linear changes in a cyclical state. The evolution of the Earth seems to then be studied in the same way as the development of chaotic theory.

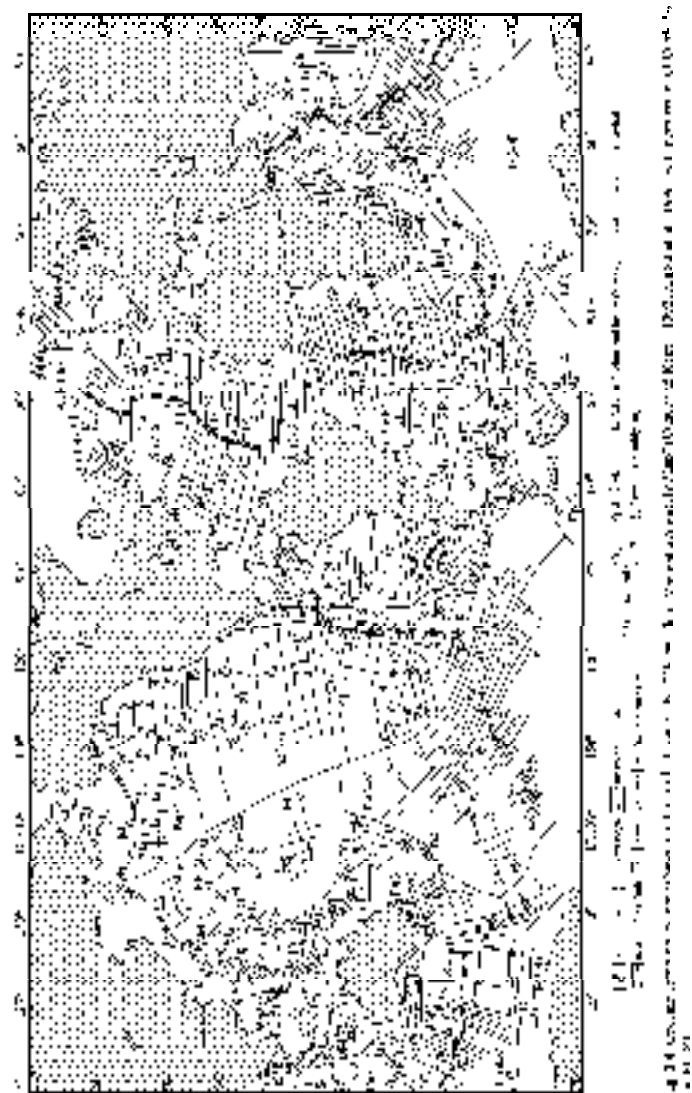

In the past two hundred years, there has been a lively theoretical debate between proponents of minor and major tectonic and geological processes have continued in much the same way and to the same rate in response to geological time (Linné, 1830; De la Bèze, 1830-1835) and proponents of catastrophism who believe that geological processes proceed by infrequent but catastrophic events (Cuvier et al., 1830). At present, most of the scientific force that wise concerns can be reconciled. It is recognized that there are such periods for periods of infrequency last for several long time span, which is the time with derive for catastrophic events, occupies a much shorter time span (Cauze et al., 1999) tectonic events represent this catastrophic period (Table 1.1).

Tectonic events are if they can resolve as their complete history is rarely presented in the geological record. The evidence is never complete, shows deformation, block displacement, vicarous tectonism and large scale uplift of the Earth's surface have resulted in widespread erosion, forming unconformities where the geological record has been destroyed. For this reason the study of tectonics did not advance very rapidly in many years of the world. In many areas, facts are few tectonic and geodynamic data are scarce; the tectonic evolution demonstrates that these deficiencies can occur over continents from Europe to much speculation and guesswork.

Table 1.2 Evolutionary evolution of the earth during six periods. All times in million years

0 - 65	2.5 cm/y
65 - 120	1.5 cm/y
120 - 180	4.5 cm/y
180 - 240	1.5 cm/y
240 - 300	3.5 cm/y
300 - 360	1.5 cm/y

1.3 Determination of Tectonic Events in the Chinese Continent

Geological data from whole China recorded in the Bureau of Geology and Mineral Resources of the PRC (1954–1999), the *Geological Gazetteer of China* (General Editorial, 1994) and the earlier researches of the author (1994), are referred to the international chrono-stratigraphic (Rehder et al., 2003; International Commission on Stratigraphy, 2004), and compiled as a table of the tectonic periods and tectonic events in China (Table 1.3).

The former practice of referring the tectonic periods in China to world-wide tectonic periods is incorrect. A division into tectonic periods and events has been revised purely for the Chinese continent.

Table 1.3. Periodic tectonic and/or seismic events (continued)

Geochronological units	Geological base	Duration of tectonic (ka)	Eastern low-velocity layer
Q ₁ -Q ₂	North American - Alaska	since 200	None
Q ₂ -Q ₃	Alaska and Yukon	20-200	Hindia
Q ₃ -P ₁	East-Missouri	90-10	East Asia

P ₉₉ -P ₁₀₀	India - India	1000-200	India

and these have been given local names (Table 1.3). However, in order to simplify the terms, and for ease of inter-continental comparison, the periods and events in this book are named directly after the geological or tectonic ages and local names for tectonic periods or events whenever possible.

As shown in Table 1.3, several tectonic periods and events are defined. The extent or duration of these tectonic periods and events is very variable. In general, much less is known about earlier periods compared with the more recent ones. Tectonic periods and events in the Caribbean and Proterozoic are somewhat broad, and periods and events in the Paleozoic can only be discussed generally, and although a series of events can be recognized, the geosynclinal data are very detailed and only two periods can be distinguished. The eight tectonic periods and events since the Paleozoic have been researched in much more detail, and as geological data are more abundant and more accurately known, one chapter is devoted to each of these periods.

In the American and Proterozoic, in the absence of detailed geosynclinal divisions, geological ages are defined in terms of tectonic units and, for the divisions are based on the tectonic-magmatic evolution of the continental crust. In the series since the Paleozoic, geological and tectonic ages or the commencement and close of each tectonic period do not coincide with the beginning and end of a period based on biocronology, and the time spans occupied by each tectonic event may be very different (Table 1.3). This is because the start and end of tectonic periods in China did not occur at

the same time as the extinction events indicated by the biostratigraphy; the climax of a tectonic period is always later than the end of corresponding extinctions.

For example, according to isotopic data from sedimentary deposits in most areas of Ukraine (see also in Table 1.1), the Ma is the most suitable age for the boundary between the Yanshanian and Cretan tectonic periods. In the international stratigraphic chart (Kozlov et al., 2010; International Commission on Stratigraphy, 2014), there are different opinions on the age of the boundary between the Jurassic and Cretaceous, ranging from 135 Ma to 146.2 Ma. From recent studies, most Ukraine researchers accept the boundary between Jurassic and Cretaceous as either 137 Ma or 144 Ma (L. Puk et al., 2010). For the age of the boundary between Jurassic and Cretaceous, the author agrees with the opinion of L. Puk et al. (2010), that is, the boundary between the Yanshanian and Cretan tectonic periods lies between early and middle Eoethers of Early Cretaceous. According to (Kozlov et al., 2010) originally (Kozlov, 1958) the age of the boundary between the Jurassic and Cretaceous for this class has not been reconsidered.

1.4 Research Principles and Methods for Interpreting Tectonic Events

1.4.1 The Rock Record

The study of tectonic events in the active and stable periods of tectonic evolution requires different search methods. Evidence for the active period of tectonic events is commonly preserved in the rocks as structural features such as folds, faults, thrusts, joints, relations and lineaments, which may be accompanied by neotectonism (a process of metamorphism). The essential changes in a rock body or in a hand specimen can be expressed in terms of the amount of deformation or strain it has undergone, i.e. reduction or expansion in volume, shortening or extension. Strain can be determined with respect to changes in the length of three mutually perpendicular principal axes of strain (ϵ_1 - maximum extension, and ϵ_2 - shortest direction; intermediate ϵ_3 - minimum compression). The largest extension ϵ_1 and ϵ_2 may be equal or have any value intermediate between ϵ_1 and ϵ_2 . Strain can be measured if the rock contains 'strain markers', objects whose original size and distribution and orientation are known and can be compared with their present size or shape (Gambrey and Jullien, 1971).

Tectonic events may also be recorded indirectly by the tectonic sedimentation. Tectonic events are commonly accompanied by uplift and subsidence, erosion, so that the sedimentary record is disrupted. However, the tectonic events may be deposited in marginal depressions or basins or in highly deformed areas as volcanoclastic (but volcanic) muds, providing a record of episodes of uplift and erosion. Tectonic events may also be accompanied by the intrusion of magmatic rocks with synchronous crystallization and associated hydrothermal (metamorphic) system.

The study of sedimentary strata can be used to solve many problems in tectonics, such as the sedimentary facies and the sequence of formation in stable basins, for the recognition of tectonic events and of episodes of strong deformation in the active tectonic period. These studies are part of a complete study of tectonics.

Methods used in the analysis of sedimentation and paleogeography are more appropriate to the stable period of a tectonic structure evolution. A stable tectonic period is represented by the deposition of a continuous sequence of sedimentary strata in a tectonically passive basin. During the stable period, variations in the thickness and rates of deposition of sedimentary strata, and changes in the rate of vertical motion of the Earth's crust, such as depression or uplift, can be recognized. By determining the sequence of strata and the rates of each sedimentary unit, it is possible to place these periods of uplift and depression in a chronological sequence and to estimate them. The structural methods of measuring the thickness of sedimentary strata and determining rates of deposition since the Mesozoic period, as shown in Appendix 2, are very approximate. There is no method of measuring the effects of tectonic depression and uplift

through great thicknesses of sedimentary rocks are most likely to be the results of multiple phases of deflexion and sedimentation and uplift-erosion. Also no allowances have been made for the effects of compaction and diagenesis, or for the influence of subsidence stress caused by later tectonic events. The study of syn-sedimentary faults is useful to determine the history or development of sedimentary basins during a stable tectonic period. A complete calculation to the account of all these factors involves an enormous amount of observations, field and laboratory work.

Although a large part of sedimentary rocks, amounting to several tens of thousands kilometers, extends over the major part of the Chinese continent, the greater part of the sediment originally deposited on the continent has been eroded away and is no longer preserved. According to statistical calculations by Kooze et al. (1984, after Durr, 1911, 1926), based on the thickness and extent of sediments and the geological ages of present-day continents, an average of 1.5 cm of sediment is deposited there about the world at a rate of 50–100 m³ per year. Mesozoic-Cenozoic sediments have been preserved on the Earth's surface, of which 50% is from the Paleozoic, 30–40% from the Proterozoic, and less than 10% from the Archean.

The accumulation of syn-sedimentary faults and especially the recognition of ecosystems are important for determining the diagenetic processes and the lithological blocks. The reconstruction of paleogeographies demonstrates the continental tectonic blocks through time and supports the tectonic concept of tectonics.

1.4.2 The Geometry of Rock Deformation

The foundation of the study of tectonics is the determination of the distribution and mutual relationships of rock units as seen in the field, together with their internal structural features such as folds, faults, lineations and foliations. Tectonics involves rock deformation on all scales from the megascopic to the microscopic, from the lithospheric scale to the individual mineral crystal and molecular lattice scale. It interrelates and then is integrated into a comprehensive tectonic system (Fig. 1.4.1). Tectonics is also concerned with the imprints on the excavation of igneous rocks and the metamorphism and the recrystallization of rock bodies with the formation of new minerals and new textures, and the relationship of these events to phases of deformation. These relationships must initially be established in the field by detailed geological mapping and geological structural surveys, sample retrieval by drill core and by deep structural fluid inclusion geochemical methods and by the study of rocks under the optical and electron microscopes.

The deformation and the displacement of the lithosphere are the main contents of the study of tectonics. Although comprehensive methods should be used in the study of tectonics, and research should encompass all branches of the geosciences, the study of rock deformation should be made on the basis of precomparisons of tectonics, which has been neglected in some recent studies.

Contributions to the knowledge and understanding of rock deformation in China during the last fifty years have been immense. It can be attributed to the exertion and success of regional geologic surveys.

In addition to an ample geological survey covering the whole Chinese continent, total geologic charts of million square kilometers at the scale of 1:1,000,000 commenced, but was not completed before 1950. Regional geologic surveys of regional geology at the scale of 1:200,000 was completed in the 1960s (for amphibious rivers), a regional geobeltic survey at the scale of 1:200,000 was carried out for river areas of China before the end of the 1950s (Bureau of Geology and Mineral Resources of PRC, 1984–1991). Now regional geologic surveys at the scale of 1:200,000 (more than 100 areas) has been completed recently over whole Qinghai-Xizang (Tibet) plateau; the results will be published shortly. These surveys raised the extent and precision of geological information substantially. Classification and comparison of regional tectonic with the description of types, scales, attitudes and the distribution of folds and faults at the macro and meso scale, and of mineralization and metamorphism built a rich foundation for studying the tectonics of China in this book.

Fig. 1.5. Relationship between stresses and geological structures

σ₁—σ₂ are the principal stresses (compression and tension), σ₃ is the total stress (Mohr's circle means fault activity), σ₁ and σ₂ are the extension of the fault, σ₃ are the lateral and vertical stresses, σ₁ and σ₂ are the horizontal and vertical stresses, σ₃ is the vertical stress.

Data concerning the geometry and attitudes of ENE-tension and west-tide folds (Fig. 10, Appendix II) have been collected and analyzed to determine regional tectonic stress orientations. In the case of the west of ENE where east-tide geological structures of the scale 1:200,000 have not yet been completed and detailed structural data are not available, geological structures of scales of 1:200,000 or 1:500,000 have been used and the strike-slip, related to anticlinal and synclinal. From these data, it can be seen that rock deformation on a widespread throughout the Chinese continent (the sphere of influence), the weakest type of rock deformation can be found even in the youngest rocks throughout China, it is difficult to find an area not affected by rock deformation.

Fig. 1.6. Number of strike-slip faults in different regions: North China (1:100,000), Middle China (1:500,000), East China (1:200,000), South China (1:200,000), Tibet (1:500,000), Xinjiang (1:200,000), Yunnan (1:200,000), Sichuan (1:200,000), Shaanxi (1:200,000), Gansu (1:200,000), Inner Mongolia (1:200,000), Qinghai (1:200,000), Ningxia (1:200,000), Henan (1:200,000), Hubei (1:200,000), Hunan (1:200,000), Anhui (1:200,000), Jiangsu (1:200,000), Zhejiang (1:200,000), Jiangxi (1:200,000), Guangdong (1:200,000), Guangxi (1:200,000), Yunnan (1:200,000), Sichuan (1:200,000), Shaanxi (1:200,000), Gansu (1:200,000), Inner Mongolia (1:200,000), Qinghai (1:200,000), Ningxia (1:200,000), Henan (1:200,000), Hubei (1:200,000), Hunan (1:200,000), Anhui (1:200,000), Jiangsu (1:200,000), Zhejiang (1:200,000), Jiangxi (1:200,000), Guangdong (1:200,000), Guangxi (1:200,000).

In all these areas, rock deformation is mainly linear with Alpidic type folds and, in areas with high and intermediate angles of dip for the faults, associated with many thrusts. In the plate areas covering half the size of China, there is a widespread deformation with inter-plate stresses, in which the angle of dip of faults is normally less than 30°, and the folds are associated with faults. These two types of deformation are transition types, belonging to the sedimentary cover detachment type, and may be called a new type. Even in stable tectonic areas covering one-third of China, which appear to have only horizontal tectonic stress, there are linear to type folds with faults with very low angles of dip, and normal faults with high angles of dip and complex joint systems.

1.4.3 The Kinematics of Blocks

The aim of tectonic studies is to examine rock deformation quantitatively, with the determination of the amounts of dilation (changes in volume), contraction (changes in shape) and translation (movements of the rock body as a whole) and the orientation of the stresses responsible for the deformation (Jin, 1993). In order to obtain the determination of the rates of deformation (rates of strain) in horizontal and/or horizontal and vertical displacement, it may be necessary to manifest the effects of multiple phases of deformation, where the orientation of the stresses may have been different in each phase. This is relatively easy if the orientation of the stresses in each tectonic period was very different, but may be difficult or even impossible if these stresses were in the same, or nearly the same direction.

Research into the kinematics of the lithosphere is aimed at determining vertical movements of uplift and depression and horizontal movements of compression, extension and strike-slip movement, and the directions in which they were assumed.

Once attention has been concentrated on vertical movements of the lithosphere with the uplift and depression of Earth's surface, the determination of vertical movements during a stable tectonic period makes use of data on variations in sea level thickness, thickness of lithology and facies transition, and may also contribute to vertical movements. Vertical movements can be determined through the study of sedimentation and erosion, transgression and regression, the up-rise of magma or changes in the thickness of the lithosphere over long periods of time. During the last one hundred years, while new methods were being perfected, it was seen that vertical movements were the major kinematic feature of the kinematics of the lithosphere.

This hypothesis is a fundamental foundation for concepts of crustal expansion, limited plate tectonics, pan-tectonism, etc. (Vare, recently). Hypotheses of one-time crustal closure (Yang, Wu et al., 1994; Wu, Liang et al., 1995), up-lift of the Mongolian Plateau (Jin et al., 1992), up-lift of the Pacific Oceanic crustal zones and thrust zones east of or underlain by (Jin et al., 1992, 1995, 1996, 1998), which have their bases in this earlier tectonic research, have exerted important influences over the development of tectonics in China. In these concepts, the tectonic evolution of continents takes place essentially as a result of vertical movements being the driving force for deformation and displacement, horizontal movements being secondary and limited in their extent. In these hypotheses, the importance of vertical movements has been more fully emphasized, in their accord with the possibility of near horizontal displacements over distances of several thousand kilometers. In these models, no explanation is offered at all for any possible horizontal displacements.

The importance of horizontal deformation and displacement was much more difficult to realize, and a model of one-time crustal closure (Li, 1974; Weidner, 1984, unpublished, 1995), first proposed the Theory of Continental Drift, based on the distribution of mass and indications of paleo-climatic zones. However, due to unexplained problems and some errors (e.g. it is impossible for the interior of continents to drift), the activities of several eminent geographers (the General Assembly of the IUGG) after detailed discussion on the International Geological Congress in 1972, the theory of continental drift was rejected. However, Weidner's hypothesis was fundamentally correct and formed one of the foundations for the development of the theory of plate tectonics in the 1960s. This year also demonstrated the difficulty of carrying out entrenched scientific thought.

Methods for determining vertical and horizontal movements of the lithospheric plates are summarized in Table 1a.

The kinematics of the lithospheric plates differ according to the movements of the plates: high angle normal to, reverse faults indicate vertical movements; intermediate and low angle faults indicate horizontal movements; characteristics of subduction or collisional tectonic zones and indicate horizontal tectonics; some low wrench (strike-slip) faults or transform faults indicate horizontal movements of the plates; intermediate and low angle normal faults and strike-slip or transform faults are characteristics of continental rift zones and oceanic ridges and indicate the oceanic extension of the plate.

Table 14 Basic and principles for various methodological examples

Geological phenomena	Methodological systems
	Basement uplift causes a reduction in thickness in post-orogenic basins Horizontal change in sedimentary facies and paleogeographic structure
Changes in sedimentary facies Tectonic position of basins and extensional basins Tectonic change of plate boundaries	Horizontal movement of sedimentary facies and basins Horizontal migration of tectonic boundaries Accretion of tectonic plates
Magnesian and calcareous composition of the crust Isotopic and geochronological (Pb-Pa path) Thermal fields High-grade metamorphism	Horizontal tectonic movement Horizontal tectonic movement Horizontal tectonic movement
High-grade metamorphism and tectonic fields	Horizontal tectonic movement

Ramsay (1967), Royce and Fisher (1971) proposed a series of methods for determining the strain involved in fold or one unroofing, and made significant progress in this field. For parameters and methods for determining vertical strain fields have not yet been developed, and it is difficult to determine rates of compression and extension in a comprehensive method of structural geology.

Smeraka (1976) first suggested that there was a relationship between the CaO content of plate composition and the chemical content $(\text{K}_2\text{O} + \text{Na}_2\text{O} + \text{CaO} + \text{MgO})$ and silicon index $(\text{Si} / (\text{Si} + \text{Al} + \text{K} + \text{Na} + \text{Ca} + \text{Mg}))$ of volcanic rocks near the subduction zone. In the formula above, the number of CaO is the percentage of weight, the number of $(\text{K}_2\text{O} + \text{Na}_2\text{O} + \text{CaO} + \text{MgO})$ are the percentage of moles (Fig. 17). Using these parameters, Smeraka (1976) discovered that the silicon index increases with increasing rates of shortening, while Nagai and Kato later used it (Fig. 17).

This relationship is not linear, but has an exponential function. These relationships are due to the relationship of rates of silica and potassium to potassium. The rate of rates of silica is very small, while the rate of rates of potassium and sodium is relatively large. When the velocity of plate movement increases and tectonic activity is enhanced, a silica index is enriched, while the rates of potassium and sodium decrease relatively (Sun et al., 1982, 1999). On the assumption that the velocities of movement involved in marginal and inner plate deformation are similar, the author (Wan et al., 1994) has used the relationship derived from the study of plate margins to quantify tectonic movements. In general, velocities of movement during inner plate deformation would be less than the rates for marginal deformation. When the velocities of plate movement for the middle of these countries are discussed, on the basis of velocities calculated from plate margins, these velocities may be slightly exaggerated. However, all the data has been treated by the same method, so that the relative magnitudes of movement velocities for different areas are measurable.

Smeraka (1976) gave only the relationship between the chemical content of volcanic rocks and the velocity of plate movement. The author has used not only the chemical composition of volcanic rocks, but also that of intrusive rocks to estimate the velocities of plate movement, while volcanic and intrusive rocks were formed at the same time in the same tectonic series. The content of iron elements in intrusive rocks, especially SiO_2 , Na_2O , K_2O , CaO , MgO , is much lower than that of associated volcanic rocks. Wang et al. (1994) has made the corresponding comparison and found that the value of plate movement velocity calculated using the content of intrusive rocks (Chen et al., 1985; Chen et al., 1986; Fu et al., 1986; Mo et al., 1991) and Wang et al. (1994, 1995) used Smeraka's method to estimate velocities of extension and compression of blocks in the Cenozoic volcanic areas of eastern China and of the Late Cenozoic volcanics in the Hengduanshan area. Using this method the
